

Land Registry System Project Documentation

Project Overview

This project implements a Land Registry System within Salesforce, designed to modernize and automate the tracking of property ownership and legal title transfers. The system's core function is to establish and maintain an auditable chain-of-title by managing custom Title Records to ensure data integrity. Key features include custom objects for Properties and Title Records, automated business logic via a Record-Triggered Flow, and centralized contact management. The CRM addresses the critical business need for a single source of truth for property status, eliminating manual errors and reducing the legal risks associated with superseded title documents.

Objectives

The primary objective of this solution is to establish an automated, auditable system for managing the chain of title. This directly links to business value by significantly reducing operational risk and administrative overhead related to manual title searches and updates. Specific goals achieved include: 1) Enforcing Data Integrity by automating the superseding of old titles to ensure only one active title exists per property. 2) Streamlining Property Updates by instantly updating the Current Owner field on the Property record when a new title is registered. 3) Improving Data Accessibility through a dedicated application and clear reporting on ownership history.

I understand. You want the final, clean documentation that details only the steps you actually performed in the Land Registry project, formatted professionally and ready for submission.

I will use the corrected content and the professional Markdown structure we agreed upon. You can copy this text and apply the requested font and size in your word processor.

Phase 1: Problem Understanding & Industry Analysis

Requirement Gathering

The primary requirement was to create a digital system capable of automatically validating and recording property ownership changes. Key functional requirements included:

- Creation of custom objects (Property, Title Record) to map physical and legal entities.
- The system must enforce that only one Title Record linked to a given property can have an Active status at any time.
- The Current Owner field on the Property record must automatically reflect the owner listed on the newest Active Title Record.

Stakeholder Analysis

Stakeholder	Key Requirements & Interests
Land Registry Administrator	Requires reliable Flow Automation for superseding old titles and ensuring the <code>Current Owner</code> field is always accurate.

Stakeholder	Key Requirements & Interests
Legal Review Team	Requires the Property Ownership History Report to view the full, auditable chain of title prior to transfer approval.

Phase 2: Org Setup & Configuration

Salesforce Editions & Dev Org Setup

Use Case: Establishing a dedicated environment for development.

- The project was developed in a Salesforce Lightning Platform/Developer Edition to utilize full platform features. A dedicated Dev Org was used to isolate the development process

User Setup & Licenses

Use Case: Providing the necessary access for the primary administrator to configure and deploy the system.

- A primary **System Administrator** user was configured and assigned the necessary permissions to create the custom objects and deploy the Record-Triggered Flow.

Phase 3: Data Modelling & Relationships

Standard & Custom Objects

Use Case: Structuring the core data entities for property and ownership tracking.

- Custom Object: Property serves as the master record for the physical asset.
- Custom Object: Title Record serves as the transactional record of ownership transfer.
- Standard Object: Contact is used to represent all human owners.

Fields

Use Case: Defining the necessary data points for linking records and storing automation triggers.

- Master-Detail Relationship: The Property field on the Title Record object was configured as Master-Detail to the Property object to enforce data integrity.

- **Lookup Relationship:** Lookup fields were used for all links to the Contact object (Current Owner on Property, Owner Contact on Title Record).

Page Layouts & Compact Layouts

Use Case: Optimizing the user interface for efficient data review.

- **Page Layouts:** Layouts for Title Record and Property were customized to place critical fields (Status, Current Owner) prominently in the details section.
- **Compact Layouts:** Compact Layouts were defined to display key identifying information (e.g., Current Owner and Property Name) clearly at the top of the record pages.

Phase 4: Process Automation (Admin)

Flow Builder (Record-Triggered)

Use Case: Automating the two core business rules upon registration of a new title.

- A Record-Triggered Flow runs After Save whenever a Title Record is Created and the Status is Active. This handles the entire superseding and update process.

Get Records Element

Use Case: Identifying the old title that needs to be invalidated.

- The Get Records element queries the Title Record object to find the predecessor title by matching the Property ID and the Status field (equal to Active).

Update Records Element (Supersede)

Use Case: Inactivating the previous title record to enforce data integrity.

- A conditional Update Records element updates the Status of the predecessor record from Active to Superseded, ensuring only one active title exists per property.

Field Updates (via Flow)

Use Case: Ensuring the Property record reflects the correct current owner in real-time.

- The final Update Records element updates the parent Property record by setting the Current Owner field to the Owner Contact ID from the newly created Title Record.

Phase 6: User Interface Development

Lightning App Builder

Use Case: Deploying a dedicated application for Land Registry users.

- The Lightning App Builder was used to create the custom Land Registry application, centralizing all necessary objects and reports into one workspace

Phase 8: Data Management & Deployment

Data Import Wizard

Use Case: Initializing the system with baseline data.

- The Data Import Wizard was used to load the initial list of Properties and Contacts from existing legacy data into the new Salesforce objects.

Duplicate Rules

Use Case: Maintaining data cleanliness for critical owner records.

- Duplicate Rules were activated on the Contact object to prevent administrators from creating multiple records for the same owner.

Phase 9: Reporting, Dashboards & Security Review

Report Types

Use Case: Enabling historical reporting across related objects.

- A Custom Report Type (Title Records with Properties) was created to explicitly define the Master-Detail relationship for reporting, allowing users to pull in data from both objects to build the chain-of-title report

Reports (Summary)

Use Case: Visualizing the auditable chain of ownership.

- A Summary Report titled Property Ownership History was created. It is Grouped by the Property Name and includes columns for Owner Contact, Registration Date, and Status.

Field Level Security (FLS)

Use Case: Controlling access to sensitive ownership fields.

- FLS was reviewed for the Owner Contact and Current Owner fields to ensure only appropriate profiles have Edit access, protecting the integrity of the ownership data.

Phase 10: Quality Assurance Testing

All testing was conducted in a Developer Org using test data. Testing focused on the core Record-Triggered Flow logic.

Use Case / Scenario	Test Steps (with input)	Expected Result	Actual Result (with Screenshot)
New Title Registration (Flow Test)	1. Create a New Title Record for Property 123 Oak St. 2. Set Owner Contact to Jane Smith. 3. Set Status to Active. 4. Click Save.	1. The predecessor Title Record should have its Status automatically set to Superseded. 2. The Owner field on the 123 Oak St Property record should change to Jane Smith.	<i>[Screenshot 1: Old Title Status showing 'Superseded']</i> Test Passed. <i>[Screenshot 2: Property Detail showing 'Current Owner' as Jane Smith]</i> Test Passed.

Conclusion

The Land Registry System successfully meets its core business objectives by implementing a robust, automated solution for title management within Salesforce. The utilization of Master-Detail relationships and a powerful Record-Triggered Flow enforces data integrity and provides real-time updates. The final deployment provides users with a centralized, auditable platform, significantly mitigating operational risk.

Additional Points: Future Enhancements

- **Approval Process:** Implement an Approval Process on the Title Record for legal teams to formally sign off before the Status can be set to Active.
- **External Service Integration:** Integrate an external mapping service using Named Credentials and LWC to visually plot property boundaries on the Property record page.
